Many functional programming languages operate on *S-expressions*. The sets of built-in functions of those languages contain *car*, *cdr*, *cons*, *atom*, *eq*, *if_then_else* functions. It is shown that Turing computable functions defined on *S-expressions* can be presented in such functional programming languages which have *car*, *cdr*, *cons*, *atom*, *eq*, *if_then_else* built-in functions. In other words, if the set of built-in constants of a functional programming language contains all these functions, then that language is Turing complete. The following two results are obtained for the minimality of the set of built-in function $\Phi = \{\text{car}, \text{cdr}, \text{cons}, \text{atom}, \text{eq}, \text{if_then_else}\}$.

1. Φ is minimal for functional programming languages which use more than two atoms.
2. The function *eq* is representable in a functional programming language which uses only two atoms and the set $\Phi \setminus \{\text{eq}\}$ of built-in functions; the set of built-in functions $\Phi \setminus \{\text{eq}\}$ is minimal for functional programming languages which use only two atoms and it is the only proper subset of the set Φ , which is minimal for such languages.
