Abstract

In this work, we compiled and cross-identified optical variability data for Roma-BZCAT blazars using nine major photometric surveys. Despite the inhomogeneous nature of these datasets, their integration provides a unique opportunity to statistically characterize blazar variability and identify extreme cases for detailed study.

Cross-identifications were performed between BZCAT and these nine catalogs, and variability parameters such as amplitude, periodicity, and light-curve morphology were analyzed across different blazar subtypes (BZB, BZG, BZQ, and BZU). Several objects exhibiting extreme variability were identified as candidates for detailed follow-up studies.

Keywords: *blazar, active galactic nuclei, variability, photometry, optical monitoring*

1. Introduction

Blazars represent a remarkable subclass of active galactic nuclei (AGN) whose relativistic jets are oriented close to our line of sight. This geometric alignment causes their radiation to be strongly Doppler-boosted, making them among the most luminous persistent sources in the Universe. The jets, powered by accretion onto supermassive black holes, emit across the entire electromagnetic spectrum – from radio to gamma rays – providing a unique laboratory for studying relativistic plasma physics, jet dynamics, and high-energy particle acceleration.

2. Data Sources and Catalog Descriptions

In this work, we utilized nine major time-domain and variability catalogs to compile optical light curves and variability metrics for blazars listed in the Roma-BZCAT catalog (Massaro et al. (2015)). Below we summarize the essential characteristics of each survey.

2.1. GCVS (General Catalogue of Variable Stars)

The GCVS (Samus' et al. (2017)) is a long-established database of variable stars maintained by the Sternberg Astronomical Institute since 1946. Version 5.1 (2017) includes ~58,000 confirmed variables with data on brightness ranges, variability types, and epochs. Although primarily stellar, GCVS provides cross-references for extragalactic variables such as blazars, aiding optical variability classification.

2.2. NSVS (Northern Sky Variability Survey)

Conducted between 1999–2000, the NSVS (Woźniak et al. (2004)) provides time-series photometry for ~14 million objects (declination $> -38^\circ$) with magnitudes 8^m – 15.5^m . Each object typically has 100–400 unfiltered CCD measurements. The cadence and sky coverage make NSVS valuable for studying short-term optical variability of bright blazars.

2.3. Catalina (CRTS/CSS)

The Catalina Real-Time Transient Survey (CRTS) ([Woźniak et al. \(2004\)](#)), based on data from the Catalina Sky Survey (CSS), covers $\sim 33,000$ deg² down to $V \approx 20$ –21 mag with hundreds of epochs per source. It is optimized for detecting transient and long-term variable phenomena, making it particularly suitable for studying blazar flares and secular trends.

2.4. Pan-STARRS (Panoramic Survey Telescope and Rapid Response System)

Pan-STARRS ([Magnier et al. \(2020\)](#)) surveyed the northern sky ($\delta > -30^\circ$) in g, r, i, z, y filters from 2010–2014, reaching ~ 22 mag with multi-epoch, multi-color photometry. Its precision enables color–magnitude and spectral variability studies of blazars.

2.5. LINEAR (Lincoln Near-Earth Asteroid Research)

Initially an asteroid survey, LINEAR ([Sesar et al. \(2013\)](#)) obtained repeated observations of ~ 20 million objects from 1998–2013 using unfiltered CCD photometry. The high cadence and long baseline are advantageous for detecting rapid or recurrent blazar outbursts.

2.6. ASAS (All-Sky Automated Survey)

ASAS-3 monitored ~ 50 million stars brighter than $V \approx 14$ mag between 2002–2009 ([Jayasinghe et al. \(2018\)](#)), providing long-term V-band light curves over the southern sky ($\delta < +28^\circ$). For bright blazars, ASAS light curves allow identification of multi-year periodic or quasi-periodic variability patterns.

2.7. TESS (Transiting Exoplanet Survey Satellite)

Although primarily designed for exoplanet detection, TESS ([Paegert et al. \(2021\)](#)) delivers high-precision (2–30 min cadence) light curves for millions of objects up to magnitude 16. Its continuous monitoring is ideal for studying intra-day blazar variability and microflares.

2.8. ZTF (Zwicky Transient Facility)

Operating since 2018 at Palomar Observatory, ZTF scans ([Fremming et al. \(2020\)](#)) the northern sky every 2–3 days in g, r, i bands down to ~ 20.5 mag, offering excellent temporal resolution for flare detection and statistical variability studies of large blazar samples.

2.9. Gaia (Global Astrometric Interferometer for Astrophysics)

The Space Gaia ([Gaia Collaboration et al. \(2023\)](#)) mission provides all-sky, multi-epoch photometry (G, BP, RP bands) and precise astrometry for ~ 1.8 billion sources down to $G \approx 21$ mag. Gaia variability classifications and high photometric accuracy make it a powerful resource for analyzing long-term blazar variability and proper motion verification.

3. Cross-identification with BZCAT

A systematic cross-match was performed between the Roma-BZCAT blazar catalog and each of the nine variability databases. The number of matched objects obtained from each catalog is summarized in Table 1.

The largest number of cross-matches was obtained with TESS, Pan-STARRS, and Gaia, reflecting their extensive sky coverage and depth. These datasets provide complementary temporal baselines, from short-term variability (TESS, ZTF) to long-term optical monitoring (Pan-STARRS, Gaia).

4. Variability Analysis

As an example, light curves were extracted primarily from the ASAS catalog for blazars exhibiting magnitude changes greater than 1 mag. For these objects, we analyzed the dependence of stellar magnitude on

Catalog	Matches
GCVS	7
NSVS	126
LINEAR	5
PanSTARRS	3049
Catalina	3
Gaia	3046
TESS	3352
ZTF	72
ASAS	74

time to identify patterns such as flaring events, quasi-periodic oscillations, and long-term trends. Preliminary results indicate that BL Lac objects tend to exhibit larger amplitude variations compared to FSRQs, consistent with their synchrotron-dominated spectra.

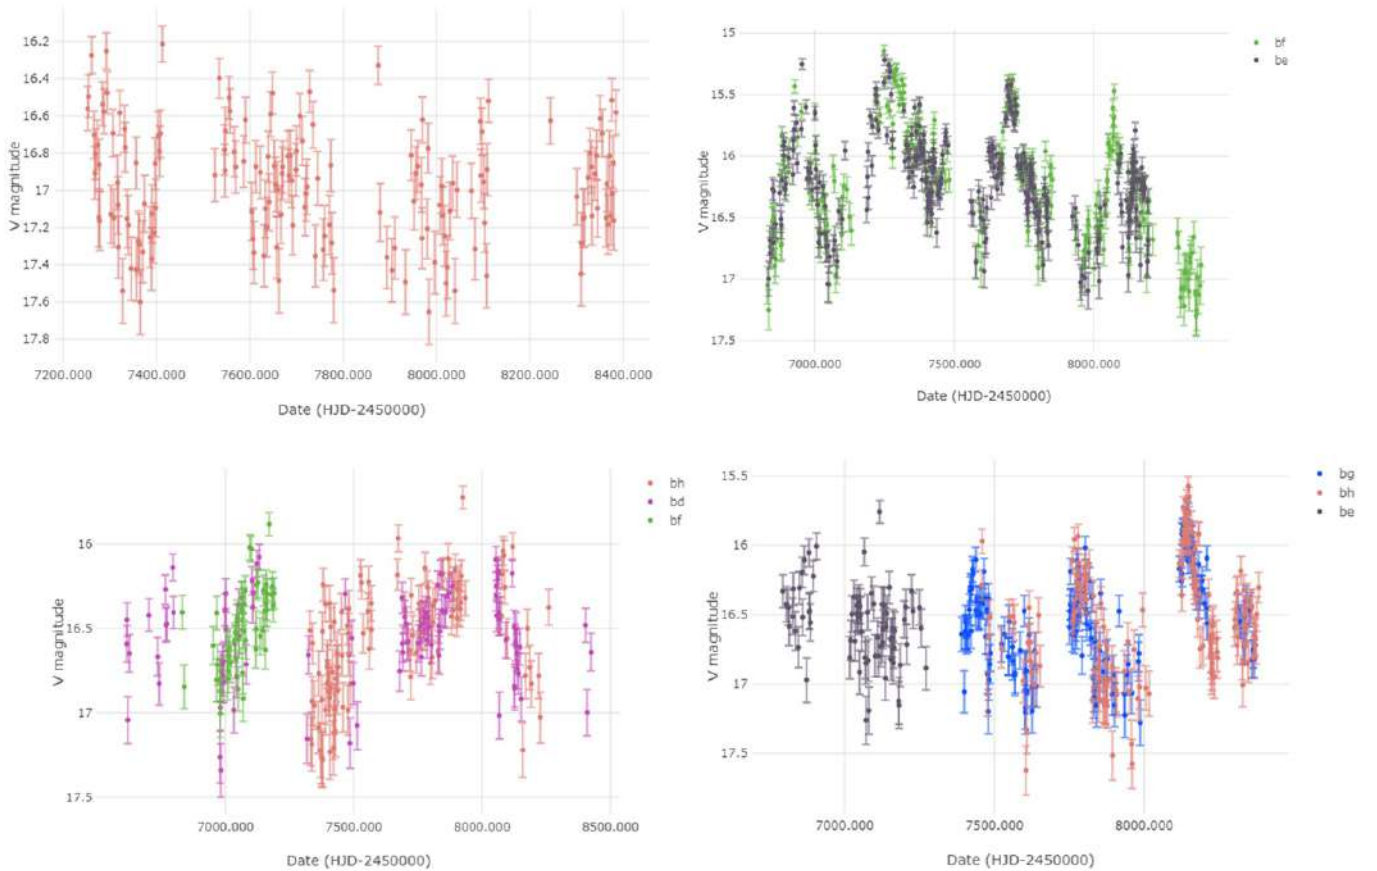

Figure 1. Variability information from ASAS

Future work will extend this analysis to include multi-survey time-series fitting and cross-band correlation analysis to better characterize variability timescales and emission mechanisms.

5. Summary and Future Work

In this study, we compiled and cross-identified optical variability data for Roma-BZCAT blazars using nine major photometric surveys. Despite the inhomogeneous nature of these datasets, their integration provides a unique opportunity to characterize blazar variability statistically and identify extreme cases for detailed study.

Our next goal is to develop a comprehensive, unified database of blazar optical variability, combining multi-epoch photometry from ground-based and space-based surveys. Such a database would fill a current

gap in time-domain astrophysics and serve as a valuable resource for studying jet physics, emission processes, and long-term variability patterns of AGN.
